Introduction

QuickServe is a web based ordering system created to make purchasing products faster, easier, and more convenient for users. Nowadays, people prefer simple and contactless ways of ordering, whether it's for food, retail items, or other services. Traditional methods like lining up or manually taking orders can take a lot of time, especially during busy hours, and can sometimes lead to mistakes. QuickServe helps solve these problems by providing a more organized and automated way of handling orders. It allows customers to browse products and place orders quickly, while also helping businesses manage their operations more efficiently. By using this system, both customers and administrators can enjoy a smoother and more reliable ordering experience. QuickServe aims to enhance convenience, reduce processing time, and provide a solution suitable for small to medium sized businesses adapting to digital transformation.

System Purpose

The system aims to simplify the ordering process by providing a digital platform where users can conveniently order products and track their purchases.

Target Users

- Customers
- Admin (Store Manager)

Key Features:

1. User Registration and Login (JWT Authentication)
2. Browse Products and View Details
3. Add to Cart and Place Orders
4. Order Management (Admin side)
5. Responsive User Interface

System Flow Explanation

- The user accesses the system through a mobile or web browser.
- The frontend (HTML, CSS, JavaScript) displays the user interface, allowing the user to browse products and interact with the system.

- When the user performs an action (e.g., placing an order), the frontend sends an HTTP request/API call to the backend.
- The backend (Node.js + Express) receives the request and processes it using appropriate API routes.
- The backend validates the request and performs necessary operations such as handling orders or retrieving product data.
- If needed, the backend communicates with the MongoDB database to store or retrieve data.
- The database processes the query and sends a data response back to the backend.
- The backend may also send requests to external APIs (e.g., payment or notification services) for additional functionality.
- The backend then sends a JSON response back to the frontend.
- The frontend updates the user interface and displays the result to the user (e.g., order confirmation)
